

SPECIFICATION

TITLE OF THE INVENTION

Producing method and apparatus of carbon nanofibers

5

TECHNICAL FIELD

The present invention relates to a producing method and apparatus of carbon nanofibers.

10 BACKGROUND ART

A carbon nanotube is a tubular carbon polyhedron having a structure where a graphite sheet is closed in a cylindrical shape. As the carbon nanotube, there are a multi-layer nanotube having a multi-layer structure where a graphite sheet is closed in a cylindrical shape and a single-layer nanotube having a single layer structure where a graphite sheet is closed in a cylindrical shape.

The multi-layer nanotube which was one of the nanotubes was discovered by Iijima in 1991. That is, it was discovered that multi-layer nanotubes were present in a carbon mass deposited on a cathode in an arc discharge process (S. Iijima, Nature, 354,56 (1991)). Thereafter, researches for the multi-layer nanotube were positively made. In recent years, the researches reached such a level that the multi-layer nanotubes could be synthesized in a large quantity.

On the other hand, the single-layer nanotube has an inner diameter of about 0.4 to 100 nanometers (nm). Reports about the

synthesis of the single-layer nanotube were simultaneously issued by Iijima and a group in IBM in 1993. The electronic state of the single-layer nanotube is predicted theoretically, and it is considered that the electronic physical properties vary from a metallic property to a 5 semiconductive property depending on how to wind a helix.

Accordingly, such a single-layer nanotube is promising as a future electronic material.

As the other applications of the single-layer nanotubes, nanoelectronics material, a field electron emitting emitter, a high 10 directionality radiation source, a soft X-ray source, one-dimensional conductive material, high heat conductive material, hydrogen occluding material and the like are considered. Further, it is thought that the application of the single-layer nanotubes is further expanded due to functional grouping of its surface, metal coating thereof and foreign 15 material including.

Conventionally, the single-layer nanotubes are produced by mixing metal such as iron, cobalt, nickel or lantanum into a carbon rod for an anode to perform arc discharge (Patent Literature 1).

In the producing method using the arc discharge, in addition to 20 the single-layer nanotubes, multi-layer nanotubes, graphite, and amorphous carbon are mixed in product, the yield of the single layer nanotubes is not only low but also fluctuation occurs in yarn diameter and yarn length of the single-layer nanotubes. Therefore, it is difficult 25 to produce single-layer nanotubes with relatively equal yarn diameters and yarn lengths.

Besides the arc discharge process, as the producing method of carbon nanotubes, a vapor phase cracking, a laser sublimation process, an electrolytic process of a condensed phase and the like have been proposed (for example, JP-A-06-280116, Japanese Patent No. 3100962, 5 JP-A-2001-520615, and JP-A-2001-139317).

However, the respective producing methods disclosed in these publications are directed to producing methods performed in a laboratory or a small-sale level, and they include such a problem that particularly the yield of carbon material is low.

10 Further, in the methods described above, it was difficult to implement a stable mass production such that producing can not be performed continuously.

On the other hand, availability of recent carbon material with nano-unit (so-called carbon nanofiber) is expected in various aspects, 15 and it is desired that the carbon material can be mass-produced industrially.

In view of the problems, the problem to be solved by the present invention is to provide a producing method and apparatus of carbon nanofibers, which allows efficient production of carbon material with 20 nano-unit by a simple process.

DISCLOSURE OF THE INVENTION

An object of the present invention is to solve at least the described problems.

25 A producing method of carbon nanofibers of the present

invention, wherein carbon nanofibers are caused to grow on surfaces of fine particles, the fine particles and fine particles with grown carbon nanofibers are recovered, the carbon nanofibers are separated from the surfaces of fine particles by a physical process or a chemical process
5 and the carbon nanofibers are recovered.

And a producing apparatus of carbon nanofibers comprising:
a reaction apparatus that supplies carbon raw material and fine particles to cause carbon nanofibers to grow on surfaces of the fine particles;
10 a heating apparatus that heats the reaction apparatus;
a recovery line that recovers fine particles on which the carbon nanofibers have grown from the reaction apparatus; and
a carbon nanofiber separating apparatus that separates carbon nanofibers from the recovered fine particles on which carbon nanofibers
15 have been grown.

The above description, and other objects, features and advantages of the present invention will be made apparent from the following detailed description of the invention.

BEST MODE FOR CARRYING OUT THE INVENTION

Embodiments of the present invention will be explained in detail below. The present invention is not limited by these embodiments.

20 A producing apparatus and a producing method of carbon nanofibers of the present invention will be explained on the following embodiments shown together with attached drawings.

25 Figs. 1 are illustrative diagrams of states where carbon nanofibers grow on fine particles. Fig. 1(a) is a status diagram where catalysts 51 are carried on surfaces of fine particles 50. Fig. 1(b) is a status diagram where carbon nanofibers 52 grow due to catalyst action.

Fig. 1(c) is a status diagram where carbon nanofibers are separated from the fine particles 50 according to a physical or chemical action.

Fig. 1(d) is a status diagram where the catalysts 51 are dissolved according to acid dissolution to obtain carbon nanofibers.

5 The producing method of carbon nanofibers of the present invention is for causing carbon nanofibers 52 to grow on surfaces of fine particles 50, recovering the fine particles 50 and the fine particles 50 with growth carbon nanofibers 52, applying physical (or mechanical) separating process to them to separate the carbon nanofibers 52 from
10 the surfaces of the fine particles 50 and recovering the carbon nanofibers 52.

15 The physical separating process means a process that, for example, using a ball mill 54 such as shown in Fig. 3 and separating the carbon nanofibers 52 from the fine particles 55 with the growth carbon nanofibers due to mechanical surface friction occurring during rotation. As shown in Figs. 1, though the carbon nanofibers 52 grow on the surfaces of the fine particles 50 like beards, they are shown with black circles (reference numeral 55) conveniently in explanation for Fig. 20 3 (the same rule applies corresponding to the following). In Fig. 3, numeral 54a denotes a sieve.

25 It is preferable that catalyst is used in order to promote growth of the carbon nanofibers. For example, as the catalyst, metal of one kind of or a combination of two or more kinds of Na, K, Mg, Ca, Sr, Ba, Cr, Mn, Fe, Co, Ni, Mo, W, Ru, Rh, Pd, Ir, Pt or lanthanoid element such as La, Ce or Pr, oxide, chloride or nitrate thereof can be used.

As alloy of the transition metal, for example, Co-Mo base catalyst metal components can be exemplified, but the present invention is not limited to these materials.

For example, thiophene as an S component can be added to the 5 catalyst as carbon nanofiber growth accelerator. The reason why the S component is added is because it is considered that the S component has a poisoning action and properly contributes to activation of catalyst.

The catalyst 51 adhered to the carbon nanofiber 52 may be removed by catalyst removing means such as acidic solution washing.

10 Another physical separating process except for the ball mill includes, for example, an ultrasonic vibrating apparatus, but the present invention is not limited to this apparatus.

In Figs. 1, the carbon nanofibers 52 grow so as to push up the catalysts 51 carried on the surface of the fine particle 50, but the growth 15 of the carbon nanofibers is not limited to such growth. As shown in Figs. 2, for example, such a case that carbon nanofibers 52 grow from catalyst carried on fine particles may occur.

In this case, the catalyst portion 51 is eventually peeled off.

20 In this invention, it is preferable that a void ratio of the fine particle is 30% or less in the physical separating process. This is because, when the void ratio exceeds 30%, porosity is large and wearing of particle surfaces proceeds in the physical separating process and it becomes difficult to separate and recover carbon nanofibers produced inside particles, which is not desirable.

25 In the present invention, in a constitution that carbon nanofibers

are separated, particularly, by the physical separating process, it is preferable that the fine particles are closely packed fine particles. The closely packed fine particle means a fine particle with high strength which is not porous. More specifically, the void ratio of the fine particle 5 may be 10% or less, preferably 5% or less, further preferably in a range of 3 to 5% and more preferably in a range of 1 to 3%. This is because further reduction in void ratio can prevent peeling-off in a fine particle during separation of carbon nanofibers so that carbon nanofibers which do not include impurities can be obtained.

10 It is preferable that the fine particles include one kind of or a mixture of two or more kinds of silica sand, aluminosilicate, zeolite aluminum oxide, zirconium oxide, silicon carbide, silicon nitride, limestone, dolomite and the like, or one kind of the compounds thereof as a main component and the main component is included in an amount 15 of 50 weight % or more.

In particular, limestone, dolomite or material including these constituent elements is suitable in use for a separating process using acid.

Particle size of the fine particles is not limited to a specific one, 20 but it is preferable that the particle size is in a range of 0.02 to 20mm, and particularly preferably in a range of 0.01 to 1.0mm.

The hardness of the fine particles can be, for example, Moh's hardness of 5 or more, preferably Moh's hardness of 8 or more (old Moh's hardness). Thereby, when carbon nanofibers are separated, 25 peeling-off on surfaces of fine particles is prevented so that only the

carbon nanofibers can be isolated.

When a fine particle 50 such as shown in Fig. 22(a) is used, since carbon nanofibers 52 can grow only from a surface of the fine particle, separation of the carbon nanofibers 52 is made easily.

5 On the other hand, when a porous fine particle 80 such as shown in Fig. 22(b) is used, when carbon nanofibers 52 together with a surface of the porous fine particle are peeled off due to undulation of a porous surface in separation of the carbon nanofibers 52, and the porous fine particle constitutes impurity, which results in low purity.

10 When catalysts 51 also adhere to inside of the porous portion 81 in a porous particle 80 as shown in Fig. 22(c) and carbon nanofibers 52 grow from the catalyst, only carbon nanofibers can not be isolated by only a physical separating process, it is necessary to first separate the entire of a corresponding portion (shown with a one-dot chain line in Fig. 15 22(c)) by a physical process and then dissolve the same by a chemical separating process such as use of acidic solution. As a result, the chemical dissolving work takes much labor and time. In particular, in soft fine particles with low hardness, much amount of fine particles are peeled off during peeling-off work, which results in increase in an 20 amount of impurities.

By using closely packed fine particles with a high strength which are not porous in this manner, wearing of the fine particles themselves is reduced in the physical separating process and the amount of catalyst can be reduced.

25 Separation is made easily by wearing and impurity in product is

much reduced so that carbon nanofibers with high purity can be obtained.

When carbon nanofibers are produced using closely packed fine particles and physical separating process is performed in this manner, 5 carbon nanofibers with impurity of 5% or less can be obtained, but when porous fine particles are used, carbon nanofibers containing impurity of 40 to 70% can only be obtained.

Since hardness becomes high by employing closely packed fine particles, peeling-off does not occur in the physical separating process 10 and recycling is effective.

Fig. 4 is a diagram for explaining a chemical separating method. As shown in Fig. 4, the producing method of carbon nanofibers using the chemical separating process is constituted so as to cause carbon nanofibers 52 to grow on surfaces of fine particles 50, recovering the 15 fine particles and fine particles 55 on which carbon nanofibers have grown, separating the carbon nanofibers 52 from the surfaces of the fine particles by chemical means using acidic solution 56, and recovering the carbon nanofibers 52.

The acidic solution 56 according to the chemical separating 20 method can include acidic solution, for example, hydrochloric acid, nitric acid, hydrofluoric acid. Further, pH of the acidic solution is 4.5 or less, preferably 4.0 or less, and further preferably, 3.5 or less.

As shown in Figs. 2, the chemical separating process according to the acidic solution is constituted so as to separate carbon nanofibers 25 52 by dissolving catalyst 51 in the case of growth of the carbon

nanofibers 52 from catalysts 51 carried by fine particles 50. As shown in Fig. 22(a), however, even when carbon nanofibers 52 grow on surfaces of fine particles so as to push up catalysts 51, acid acts on boundary faces between the fine particles 50 and the carbon nanofibers 52, which results in separation of the carbon nanofibers.

In the present invention, as shown in Fig. 5, the fine particles 50 from which the carbon nanofibers 52 have been separated can be recycled. Regarding some loss of the fine particles, fine particles 50 may be further replenished.

10 The method for causing fine particles 50 to carry catalyst 51 is not limited to a specific one, but there is a method shown in Fig. 6 or Fig. 7.

As shown in Fig. 6, first, adhesion of catalyst 51 to fine particles 50 may be achieved by charging fine particles 50 into a catalyst 15 carrying vessel 60 or supplying them to the vessel from a fine particle supplying device, and spraying catalyst containing liquid 62 from a spraying unit 63 to carry the catalyst 51 on surfaces of the fine particles 50. Such a constitution is employed that the catalyst is efficiently adhered to surfaces of the fine particles by supplying fluidized gas 64 20 into the catalyst carrying vessel 60 from a lower portion thereof to put the fine particles 50 in a fluidized state.

As shown in Fig. 7, such a constitution may be employed that a spraying unit 63 that sprays catalyst containing liquid 62 is provided inside a rotary kiln 66 and adhesion of catalyst 51 is performed while 25 rotating fine particles 50.

As shown in Fig. 8, such a constitution is employed that carbon nanofibers 52 are caused to grow on surfaces of the fine particles 50 via catalyst 51, the fine particles and fine particles 55 on which carbon nanofibers have grown are recovered, the carbon nanofibers 52 are 5 separated from surfaces of the fine particles 50 by the chemical separating process using acidic solution 56, the carbon nanofibers 52 is recovered and catalyst solution 58 resolved in the acidic solution is recycled. Regarding some loss of the catalyst solution, catalyst solution 58 may be further replenished.

10 That is, since particle diameters of the fine particles 50 are large, the fine particles are separated using a sieve with such a mesh size that carbon nanofibers 52 floating in the acidic solution 56 pass, and then the carbon nanofibers 52 are separated from the acidic solution 56. Fine particles separated after acid process are caused to carry catalyst 15 again to be recycled for production of next carbon nanofibers. Further, catalyst in the acidic solution 56 can be recycled by causing fine particles 50 to carry the catalyst again.

At that time, by employing fine particles 50 with excellent acid solubility, such a constitution may be employed that not only catalyst 51 20 but also the fine particles 50 are dissolved and processed so that only carbon nanofibers 52 are present in acidic solution.

This aspect is shown in Fig. 9. As shown in Fig. 9, after carbon nanofibers 52 that are present in catalyst and fine particles dissolved solution 56 dissolved with catalyst and fine particles are removed, 25 catalyst and fine particles corresponding to loss are replenished. Next,

the catalyst and fine particles dissolved solution 59 is dried. At that time, after heating and baking are conducted to obtain viscous granulates, fine particles 50 with desired particle diameters are prepared. Thereafter, catalyst component is carried on surfaces of fine 5 particles under a reducing atmosphere. The fine particles carrying catalyst are recycled for production of carbon nanofibers, again.

As shown in Fig. 10, after carbon nanofibers 52 present in the catalyst and fine particles dissolved solution 59 dissolved with catalyst and fine particles are removed, a separating processing of catalyst 10 dissolved solution 59a and fine particles dissolved solution 59b is performed. The separating process can include, for example, a separating process depending on a difference in pH using a solubility product or a separating process utilizing an ion exchange membrane.

Catalyst and fine particles from the catalyst dissolved solution 15 59a and the fine particles dissolved solution 59b separated respectively, are subjected to reproducing processes with respective additions of corresponding losses. The catalyst composing process can include, for example, a drying process performed for several hours at a temperature of 120°C, a high temperature baking process conducted at 20 a temperature of 700 to 800°C or a metallization process of catalyst conducted by a hydrogen reducing process, but it is not limited to these processes. Further, after heating and baking are performed to obtain viscous granulates from the fine particle dissolving solution 59b, fine particles 50 with desired particle diameters are produced.

25 Though the reaction method of carbon nanofibers is not limited

to a specific one, examples of the producing method are shown, for example, in Fig. 11 to Fig. 15. For example, a case shown in Fig. 11 is a producing method of carbon nanofibers of a fluidizing layer system that charges fine particles 50 constituting fluidizing material inside a 5 fluidizing furnace 71 to fluidize them and feeds raw material gas 72 in the fluidizing furnace 71 from a lower portion thereof to draw out the fluidizing furnace upwardly to conduct reaction. Further, the producing method may be of a circulating fluidizing bed type. A case shown in Fig. 12 is a producing method of carbon nanofibers of a moving layer 10 system that charges fine particles 50 into a moving bed furnace 73 to gradually charge fine particles and draw out portion thereof, and charges raw material gas 72 from a lower portion of the furnace to draw it upwardly to conduct reaction. A case shown in Fig. 13 is a producing method of carbon nanofibers of a fixed bed system that 15 charges raw material gas 72 into a fixed bed furnace 74 from a lower portion thereof and draws out it upwardly to conduct reaction. A case shown in Fig. 14 is a producing method of carbon nanofibers of a gas flow bed system that charges fine particles 50 along with raw material gas 72 from one end of a vapor phase reaction furnace 75 to conduct 20 reaction and recovers reaction product at the other end thereof. At that time, catalyst may be carried on fine particles in advance or catalyst may be charged separately, and the charging method of catalyst is not limited to a specific one.

As shown in Fig. 15, such a constitution may be employed that 25 fine particles 50 to be supplied inside are pre-heated in a preheating

furnace 76, and they are then supplied to a gas phase reaction furnace 75 having a heating apparatus 77, so that uniformity of the reaction temperature is achieved owing to heat capacity of the fine particles preheated and a reaction is made properly.

5 Next, Fig. 16 is a diagram of a specific example of a carbon nanofiber producing apparatus that produces carbon nanofibers. As shown in Fig. 16, the producing apparatus of carbon nanofibers is provided with a fluidizing layer reaction unit 12 charged therein with fine particles carrying catalyst 51 that are fluidizing material, a raw material 10 supplying apparatus 14 that supplies carbon material 13 that is raw material gas into the fluidizing layer reaction unit 12, a catalyst carrying fine particles supplying apparatus 16 that supplies fine particles 50 carrying catalyst 51 into the fluidizing layer reaction unit 12, a free board unit 17 having a space where the fine particles which are 15 fluidizing material in the fluidizing layer reaction unit 12 scatter or flow down, a fluidizing gas supplying apparatus 19 that supplies fluidizing gas 18 that fluidizes the fluidizing material 11 inside, a heating apparatus 20 that heats the fluidizing layer reaction unit 12, a recovery line 23 that recovers carbon nanofibers 52 and fine particles 50 20 scattered from the free board unit 17, a separating apparatus 24 that separates the fine recovered particles 50 recovered in the recovery line 23 and carbon nanofibers 52 from each other, and a refining unit 27 that removes catalyst adhered to the carbon nanofibers 52..

As a fluidized bed reaction type of the fluidizing layer reaction 25 unit 12, there are a bubble type fluidizing layer type and a jetting type

fluidizing layer type, and either one thereof can be used in this invention.

In this embodiment, the fluidizing layer reaction unit 12 and the free board unit 17 constitute a fluidizing layer reaction vessel 25.

5 Further, it is preferable that the free board unit 17 has a flow path unit area larger than that of the fluidizing layer reaction unit 12.

The carbon raw material 13 supplied from the carbon material supplying unit 14 may be any one of compounds containing carbon, and it can include not only CO and CO₂ but also alkanes such as methane, 10 ethane, propane and hexane, unsaturated organic compound such as ethylene, propylene and acetylene, aromatic compound such as benzene or toluene, polymer material such as polyethylene or polypropylene, or oil, or coal (including coal converted gas), but the present invention is not limited to these materials. Further, organic 15 compound containing not only C or H but also S component or Cl component may be used.

The carbon material 13 is supplied to the fluidizing layer reaction unit 12 in a gaseous state and is subjected to a uniform reaction by stirring conducted by the fine particles 50 which are the 20 fluidizing material, thereby causing carbon nanofibers to grow. At that time, inert gas is separately introduced as fluidizing gas from the fluidizing gas supplying apparatus 19 to the fluidizing layer reaction unit 17.

Supplying of the catalyst is not only performed by carrying 25 catalyst on surfaces of fine particles in advance but also catalyst 51

may be supplied into the reaction apparatus in a liquid state where the catalyst 51 is dissolved in carbon material 13. In this case, such a constitution may be employed that the catalyst carrying fine particle supplying apparatus 16 is simply a supplying apparatus for fine particles 50 and the raw material supplying apparatus 14 is a unit that supplies catalyst in a liquid state.

Catalyst may be supplied to the reaction apparatus in a solid or gaseous state. In this case, a catalyst supplying apparatus may be provided separately.

10 Carbon fibers are synthesized by setting a temperature range of 300°C to 1300°C, and more preferably 400°C to 1200°C and causing carbon material such as benzene to contact with catalyst for a fixed time in mixed gas with a hydrogen partial pressure of 0% to 90%.

As the separating apparatus 24, not only a cyclone but also, for 15 example, a known separating apparatus such as a bug filter, a ceramic filter or a sieve can be used.

Such a constitution is employed that the carbon nanofibers 22 separated by the separating apparatus 24 are recovered as carbon nanofiber pure product by the refining unit 27 separating adhered 20 catalyst from the carbon nanofibers. As the refining unit 27, for example, a known filtering unit such as a bug filter can be used.

In the fluidizing layer reaction apparatus, thus, fine particles carrying catalyst are used as the fluidizing material, carbon nanofibers are caused to grow on surfaces of carbon nanofibers, carbon nanofibers 25 are separated by collisions among the fine particles caused

simultaneously with the growth of the carbon nanofibers, so that the carbon nanofibers can be recovered as product.

Catalyst 51 may be separately supplied to the fluidizing layer reaction unit 12. Thereby, catalyst of an amount exceeding the amount 5 of catalyst carried by the fine particles is present, which can result in improvement of a reaction efficiency.

An outline of another producing apparatus of carbon nanofibers is shown in Fig. 26. The apparatus of this embodiment is constituted so as to adjust fine particles carrying catalyst, which is supplied to the 10 fluidizing layer reaction unit 12, in a catalyst carrying apparatus in advance and supply the adjusted fine particles to the fluidizing layer reaction unit 12. Like members in the producing method of carbon nanofibers shown in Fig. 16 are attached with signs and explanation thereof will be omitted.

15 As shown in Fig. 26, the producing apparatus of carbon nanofibers according to this embodiment is provided with a catalyst carrying apparatus 60 that causes fluidizing material 11 to carry catalyst 12, the fluidizing layer reaction unit 17 that supplies the catalyst carrying fluidizing material 67 carrying catalyst 51 obtained in the 20 catalyst carrying apparatus 60 and carbon material 13 to produce carbon nanofibers, the free board unit 18 having a space that communicates with the fluidizing layer reaction unit 17, through which the fluidizing material inside the fluidizing layer reaction unit scatters and flows down, a fluidizing gas supplying apparatus 20 that introduces 25 fluidizing gas 19 fluidizing the catalyst carrying fluidizing material 14

into the fluidizing layer reaction unit 17 to supply it thereto, heating apparatus 21 that heats the fluidizing layer reaction unit 17, the recovery line 23 that recovers catalyst carrying fluidizing material scattered from the free board unit 18, which has grown carbon 5 nanofibers, and a cyclone that is the separating apparatus 25 separating the carbon nanofibers 52 from the fluidizing material recovered in the recovery line 23.

The catalyst carrying apparatus 60 is provided with a fluidizing material supplying apparatus 62 that supplies the fluidizing material 11 into a carrying vessel main body 61, and a spraying unit 63 that sprays catalyst 12 to the fluidizing material 11 supplied into the carrying vessel main body 61.

In the carrying apparatus shown in Fig. 27, an aspect where catalyst is carried on the fluidizing material is shown illustratively. As 15 shown in Fig. 26 and Fig. 27, such a constitution is employed that catalyst carrying fluidizing material 67 carrying catalyst 51 can be obtained by spraying catalyst 51 consisting essentially of metal components 66 dispersed in solvent 65 to the fluidizing material 11 separately supplied by the fluidizing material supplying apparatus 62 20 from the spraying unit 63.

The carbon nanofibers 52 grown on the catalyst 12 carried on the fluidizing material 22 separated by the cyclone which is the separating apparatus 25 are separated into the carbon nanofibers 52, the metal components 66 and the fluidizing material 11 by separating 25 apparatus 68 separately set. The separated metal components 66 are

recycled as raw material for catalyst again.

In this embodiment, thus, since the catalyst 51 is carried on the fluidizing material 11 in advance to prepare the catalyst carrying fluidizing material 67, which is supplied to the fluidizing layer reaction unit 17, uniform reaction of carbon raw material can be conducted within the fluidizing layer and carbon nanofibers 52 can be produced stably.

As shown in Fig. 17, by providing a pressurizing unit 21 that pressurizes interior of the fluidizing layer reaction unit 12, a pressurizing condition can be achieved therein. By setting the fluidizing layer reaction unit 12 to the pressurized condition, a reaction efficiency can be improved and a producing efficiency of carbon nanofibers can also be improved.

The pressurizing unit 21 can include, for example, liquefied nitrogen, and the fluidizing material supplying apparatus 26, the raw material supplying apparatus 14, the fluidizing gas supplying apparatus 19, and the catalyst carrying particle supplying apparatus 16 are pressurized by a pressure-adjusting valve 28 and a carburetor 29.

The pressurizing condition meets 0.01 MPa or more, preferably 0.5 MPa, and more preferably 2MPa. It is preferable that the upper limit is set to 3MPa. By setting the pressurizing condition to 0.01MPa or more, a fast reaction speed can be achieved so that the reaction efficiency can be improved. A deposition condition for carbon nanofibers can be controlled according to the pressurized condition. When the pressurized condition exceeds 3MPa, a pressure proof

reference for apparatuses and peripheral devices becomes high and manufacturing costs thereof increases, which is not desirable. By setting the interior of the fluidizing layer reaction unit 12 to the pressurizing condition in this manner, the reaction efficiency can be 5 improved.

As shown in Fig. 18, different reaction conditions may be set such that a calm fluidizing layer is formed under a first reaction condition by changing a flow rate of the fluidizing gas 18 supplied to the fluidizing layer reaction unit 12 and a urgent fluidizing layer is formed 10 under a second reaction condition.

Thereby, after reaction is caused to progress in a state that the fine particles stay in the calm fluidizing layer for a fixed time, the fine particles are moved to the urgent fluidizing layer, where the fine particles are violently stirred by fluidizing gas 18 with a rapid flow rate 15 to cause wearing among fine particles, so that carbon nanofibers 52 produced on surfaces of the fine particles are separated and discharged externally as product 32 together with exhaust gas 33, and the carbon nanofibers may be recovered.

As shown in Fig. 44, for example, when particle diameter is in a 20 range of 50 to 60 μm , a reaction condition for the calm fluidizing layer means a flow rate in a region from a uniform phase fluidization of about 0.002 to 0.04 m/s to a low flow rate side in a bubble fluidization, while a reaction condition for the urgent fluidizing layer means a flow rate ranging from a turbulence fluidization of about 0.1 to 1.0 m/s to a high 25 flow rate side in the bubble fluidization.

As shown in Fig. 19, such a constitution may be employed that interior of the fluidizing layer reaction unit 12 is partitioned to two portions by a partition member 31, and reaction conditions are made different by changing the flow rate of the fluidizing gas 18 such that one 5 portion is a calm fluidizing layer 12A and the other portion is an urgent fluidizing layer 12B. Thereby, after reaction is caused to progress in a state that the fine particles stay in the calm fluidizing layer 12A for a fixed time, the fine particles are moved to the urgent fluidizing layer 12B, where the fine particles are violently stirred by fluidizing gas 18 with a 10 rapid flow rate to cause wearing among fine particles, so that carbon nanofibers 52 produced on surfaces of the fine particles are separated and discharged externally as product 32 together with exhaust gas 33, and the carbon nanofibers 52 may be recovered.

As shown in Fig. 20, such a constitution may be employed that 15 interior of the fluidizing layer reaction unit 12 is partitioned to a plurality of portions by partition plates 41A to 41H so that a staying time distribution of fine particles in each fluidizing layer is made small.

As shown in Fig. 21, such a constitution may be employed that a plurality of fluidizing layer reaction containers 25A to 25D are provided 20 and reacted particles are gradually drawn out of each fluidizing layer reaction containers 25A to 25D, so that a particle staying time distribution is made small. Such a constitution is employed that drawing-out of particles is conducted from a furnace bottom portion of the fluidizing layer reaction container 25D.

25 Such a constitution is employed that the product 32 and the

exhaust gas 33 are individually recovered from each fluidizing layer reaction container and carbon nanofibers are refined.

As shown in Fig. 23, such a constitution may be employed that additive particles 91 for peeling off carbon nanofibers that are different 5 in shape, size and material from the catalysts are charged into the fluidizing layer reaction unit 12 so that carbon nanofibers are separated.

The additive particles 91 for peeling off carbon nanofibers may be prepared by properly combining additive particles which are equal in shape to the catalysts but different in diameter therefrom, ones which 10 are different in shape therefrom, ones which are different in material therefrom, and ones which are different in particle diameter therefrom with one another.

For example, when the shape of catalyst particles is spherical, additive particles may be cubic. With such a constitution, when 15 particles contact with one another, local collision cause a large impact partially, which promotes peeling-off of carbon nanofibers from the catalyst particles.

For example, such a constitution may be employed that fine particles are made of high strength ceramics and additive particles 91 20 are columns made from stainless steel. In the fluidizing layer reaction unit 12, the additive particles 91 of the stainless steel column give impact on carbon nanofibers to promote peeling-off. On the other hand, since additive particles 91 of the stainless column are softer than the ceramics with high strength, the high strength ceramics are 25 prevented from being worn. Since much thin pieces of stainless steel

are included in particles scattered from the fluidizing layer and thin pieces of the high strength ceramics are reduced, so that a carbon nanofiber concentration can be improved easily by acid processing in scattered particles.

5 By using magnetic material (for example, cobalt-base alloy material) as the additive particles for peeling-off, the purity of carbon nanofibers can be improved by separation utilizing magnetic force.

Such a constitution can be employed that, as the additive particles, ones having particle diameters smaller than those of fine 10 particles are used to form a fluidizing layer, and fine particles adhered with catalysts are supplied from an upper portion of the fluidizing layer, and carbon nanofibers are caused to grow while large catalyst particles are settling, so that carbon nanofibers are peeled off. A settling time can be controlled according to a difference of particle diameter between 15 the particles so that the reaction time can be adjusted.

Such a constitution can be employed that an eddy flow is formed in advance near a lower end of the fluidizing layer reaction unit 12, and when catalyst particles with grown carbon nanofibers settles, collision among particles are promoted by impact of the eddy flow, so that 20 peeling-off of the carbon nanofibers are promoted. Fluidizing may be supplied in a tangential direction in order to form the eddy flow, and for example, an eddy flow perforated plate may be formed on a lower portion side of the fluidizing layer reaction unit 12.

By charging additive particles for peeling-off inside the reaction 25 layer, wearing promotion can be achieved in the fluidizing layer reaction,

and by using additive particles made of stainless steel or the like and dissolved in acid at a time of separation, a separation efficiency is increased so that improvement in impurity of carbon nanofibers can be attained. By changing particle diameters of fine particles properly, 5 control on a staying time of the fine particles carrying catalysts inside the fluidizing layer can be made possible so that the reaction time can be controlled arbitrarily.

By forming the additive particles from magnetic material, separation utilizing magnetic force can be made possible after the 10 particles are recovered.

As shown in Fig. 24, by arranging baffles 92, which are collision plates, in a direction perpendicular to a fluidization direction inside the fluidizing layer reaction unit 12, the number of collisions is increased during fluidization so that a peeling-off efficiency of carbon nanofibers is 15 improved.

The baffle plate 92 may be constituted so as to also function as a heat transfer tube heating interior of the fluidizing layer reaction unit.

As shown in Fig. 25, such a constitution may be employed that fine particles 55 with carbon nanofibers grown by the reaction are 20 recovered to be washed with acidic solution 56, organic compound solution 96 obtained by mixing additives 93 having functional groups with high affinity with carbon nanofibers or having functional groups with lipophilic property and organic compound 94 which is liquid in the normal temperature is then added in acidic solution 56 including 25 produced carbon nanofibers, carbon nanofiber dispersion 95 enclosed

by the additive 93 is dispersed in the organic compound solution 96, acidic solution 56 and fine particles 50 from which the carbon nanofibers have been peeled off are then removed, organic compound solution including the carbon nanofiber dispersion 95 is heated, the 5 additives 93 which are micelle particles 97 constituted of aggregation of the additives and the carbon nanofibers 52 are separated, and thereafter the additives 93 and the organic solvent 94 are recovered to obtain pure product of carbon nanofibers 52.

It is preferable that the functional group with high affinity with 10 carbon nanofibers a compound having a polynuclear aromatic functional group. The compound having a polynuclear aromatic functional group includes, for example, either one of anthracene, pyrene and chrysene, or a mixture thereof. The organic compound which is liquefied in the normal temperature includes, for example, either one of normal hexane, 15 toluene, tetrahydrofuran, dimethylformamide, chloromethane, and the like, or a combination of at least two thereof.

By using additives whose affinity between the organic compound and the carbon nanofibers varies according to a temperature condition and elevating a temperature, the affinity between the additives and the 20 carbon nanofibers is lost and the additives 96 aggregated in the micelle state are dissolved in the organic solvent 94 so that carbon nanofibers are isolated. Thereafter, the organic solvent and the additives are vaporized and recovered. As a result, the carbon nanofibers can be isolated and the additives can also be recovered, so that the additives 25 can be recycled.

As described above, according to the present invention, by producing carbon nanofibers using fine particles, carbon nanofibers with a high purity can be produced efficiently with a high yield. As a result, an industrial mass production of carbon nanofibers is made 5 possible, and inexpensive carbon nanofibers can be produced.

Next, a case that catalysts are individually charged in a reaction apparatus using a fluidizing layer to produce carbon nanofibers will be explained with reference to Fig. 28. Like members in the carbon nanofiber producing apparatus explained with reference to Fig. 16 are 10 denoted by signs and explanation thereof will be omitted.

Fig. 28 is a diagram of another example of an apparatus for producing carbon nanofibers.

As shown in Fig. 28, the producing apparatus of carbon nanofibers is provided with the fluidizing layer reaction unit 12 in which 15 fluidizing material 11 has been charged, the raw carbon material supplying apparatus 14 that supplies raw material 13 into the fluidizing layer reaction unit 12, a catalyst supplying apparatus 101 that supplies metal catalysts 51 into the fluidizing layer reaction unit 12, the free board unit 17 having a space in which fluidizing material 11 inside the 20 fluidizing layer reaction unit 12 scatters and flow down, the fluidizing gas supplying apparatus 19 that supplies fluidizing gas 18 fluidizing the fluidizing material 11 inside the fluidizing layer reaction unit 12, the heating apparatus 20 that heats the fluidizing layer reaction unit 12, a pressurizing unit 102 that pressurizes interior of the fluidizing layer 25 reaction unit 12, the recovery line 23 that recovers carbon nanofibers

52 and the fluidizing material 11 scattered from the free board unit 17, and the separating apparatus 24 that separates the fluidizing material 11 and the carbon nanofibers 52 recovered in the recovery line 23. In Fig. 27, numeral 103 denotes a pressure-adjusting valve and 104 5 denotes a carburetor, respectively.

The pressurizing unit 102 includes, for example, liquefied nitrogen, and the fluidizing material supplying apparatus 105 which supplies the fluidizing material 11, the raw material supplying apparatus 14, the fluidizing material gas supplying apparatus 19 and the catalyst 10 supplying apparatus 101 are pressurized by the carburetor 104. The pressurizing condition is preferably 0.5MPa or more, and more 10 preferably 2MPa.

The upper limit of the pressurizing condition should be set to 3MPa. This is because, by setting the pressurizing condition to 15 0.5MPa or more, a fast reaction speed can be obtained so that the reaction efficiency can be improved. By adjusting the pressurizing condition, the precipitation condition of carbon nanofibers can be controlled. When the pressurizing condition exceeds 3MPa, a pressure proof reference for apparatuses and peripheral devices 20 becomes high and manufacturing costs thereof increases, which is not desirable.

By setting the interior of the fluidizing layer reaction unit 12 to the pressurizing condition, the reaction efficiency can be improved.

One example of another apparatus for producing carbon 25 nanofibers is shown in Fig. 29. As shown in Fig. 29, the producing

apparatus of carbon nanofibers has such constitution that a CO supplying apparatus 106 that supplies CO into the fluidizing layer reaction unit 12 is provided in the apparatus shown in Fig. 28.

When the obtained carbon nanofibers 52 are present alone, 5 refining is not required, but since carbon nanofibers adhere to fluidizing material or the reaction unit 12, after reaction is terminated, the catalyst 51 disappears as $\text{Fe}(\text{CO})_5$ to refine the carbon nanofibers 52 by continuing the pressurizing by the pressurizing unit 21 without a break to supply CO from the CO supplying apparatus 31, as shown in Fig. 30 10 and Fig. 31.

After the carbon nanofibers 52 are put in a separated state in this manner, they are separated by the separating apparatus 24, the carbon nanofibers 52 and the fluidizing material 11 are separated and the carbon nanofibers 22 are recovered as they are.

15 The refining condition is satisfied by conducting temperature control such that at least the vapor pressure attains a temperature obtained at 0.01MPa (atmospheric pressure of 0.1) or more. As the temperature condition, for example, a temperature control may be made to the boiling point (102.5°C) of the temperature $\text{Fe}(\text{CO})_5$, and it is 20 desirable that the temperature is kept at the boiling point or more. It is preferable that the pressurizing condition at that time is in a range of 0.01 to 2.5MPa (0.1 to 25 atmospheric pressure).

As a result, since the catalyst metal component disappears, the fluidizing material can be recycled and since the obtained carbon 25 nanofibers do not adhere to the metal catalyst, the carbon nanofibers

with high purity can be obtained.

When the carbonyl is added, the pressurizing unit 102 is omitted, and producing carbon nanofibers in the fluidizing layer reaction unit 12 can be made in the normal condition.

5 Such a constitution may be employed that, by making the pressurizing condition in isolation refining of carbon nanofibers conducted by the fluidizing layer reaction apparatus larger than that in production of carbon nanofibers, the disappearing efficiency is improved.

10 Fig. 32 is a diagram of one example of another apparatus of carbon nanofibers. Same constitutions as those shown in Fig. 29 are attached with same numerals, and explanation thereof will be omitted. As shown in Fig. 30, the producing apparatus of carbon nanofibers is provided with the fluidizing layer reaction unit 12 in which fluidizing 15 material 11 has been charged, the raw material supplying apparatus 14 that supplies carbon material 13 into the fluidizing layer reaction unit 12, a catalyst supplying apparatus 101 that supplies catalyst 51 into the fluidizing layer reaction unit 12, the free board unit 17 having a space in which the fluidizing material 11 inside the fluidizing layer reaction unit 20 12 scatters or flows down, the fluidizing gas supplying apparatus 19 that introduces fluidizing gas 18 fluidizing the fluidizing material 11 inside the fluidizing layer reaction unit 12 to supply the same therein, the heating apparatus 20 that heats the fluidizing layer reaction unit 12, a pressurizing vessel 111 that pressurizes carbon nanofibers 22 25 produced in the fluidizing layer reaction unit 12 after the carbon

nanofibers 22 are conveyed by a conveying line 110 together with the fluidizing material 11, a CO supplying apparatus 106 that supplies CO (carbonyl) into the pressurizing vessel 111, the recovery line 23 that that recovers separated carbon nanofibers 52 and fluidizing material 11 5 from the pressurizing vessel 111, and the separating apparatus 24 that separates the fluidizing material 11 and the carbon nanofibers 52 recovered in the recovery line 23 from each other.

In the producing apparatus of carbon nanofibers, after carbon nanofibers are moved into the pressurized vessel 111, producing carbon 10 nanofibers and refining carbon nanofibers are performed separately by supplying CO (carbonyl) from the CO supplying apparatus 106.

Next, in the producing apparatus of carbon nanofibers of the present invention, improvement of the free board unit constituting the reaction unit will be explained.

15 Fig. 33 is a diagram of an outline of another producing apparatus of carbon nanofibers. Same members as those shown in Fig. 16 are attached with same numerals, and explanation thereof will be omitted. As shown in Fig. 33, the producing apparatus of carbon nanofibers according to this embodiment is provided with a fluidizing 20 layer reaction unit 12 that supplies carbon material 13, catalyst 51 and fluidizing material 11 to produce carbon nanofibers 52, a free board unit 17 that has a space communicating with the fluidizing layer reaction unit 12, through which fluidizing material 11 scatters and flows down, the fluidizing gas supplying apparatus 19 that introduces fluidizing gas 18 25 fluidizing fluidizing material 11 into the fluidizing layer reaction unit 12

to supply the same, the heating apparatus 20 that heats the fluidizing layer reaction unit 12 from the periphery thereof, the recovery line 23 that recovers fluidizing material 11 and carbon nanofibers 52 scattered from the free board unit 17, and the separating apparatus 24 that

5 separates the fluidizing material 11 and the carbon nanofibers 52 recovered by the recovery line 23. Further, partition members 121 dividing interior of the free board unit 17 into plural portions (six chambers in this embodiment) are hung from a free board top portion to divide the interior into chambers 122 – 1 to 122 – 6 that are opened at

10 their lower ends, a plurality of recovery lines 123 – 1 to 123 – 6 that cause the recovery line 23 and respective chambers separated to communicate with each other is provided and opening/closing valves 124 – 1 to 124 – 6 that open/close flow paths of the respective recovery lines are provided.

15 By supplying carbon material 13, catalyst 51 and fluidizing material 11 to the fluidizing layer reaction unit 12, respectively, and supplying fluidizing material gas 18 to fluidize the fluidizing material 11, and by setting predetermined pressure and temperature, a uniform reaction is performed by the fluidizing layer, which results in production

20 of carbon nanofibers 52.

When the fluidizing material 11 with a particle diameter of, for example, about 200 μ m is used, as shown in Fig. 40, a flow rate in the fluidizing layer is about 0.1m/s, and a flow rate in the free board portion 17 is about 0.01m/s. In this case, all valves 124 – 1 to 124 – 6

25 interposed in the recovery line 123 – 1 to 123 – 6 in communication with

the respective chambers 122 - 1 to 122 - 6 formed in the free board portion 17 are put in an open state. Producing of carbon nanofibers is performed in such a state.

In a stage where produced carbon nanofibers adhere to a wall 5 face of the chambers or the like and adhered material has been accumulated in a predetermined amount, for example, the first recovery line 123 - 1 is limited and the other valves in the recovery lines 123 - 2 to 123 - 6 are put in a closed state, a flow rate of the fluidizing material 11 in the fluidizing layer reaction unit 12 is increased so that the 10 fluidizing material splashed from the fluidizing layer to fly out is positively transported to an upper portion of the free board unit 17. Since some of particles transported drop along a wall face inside the flow path, the adhered material is worn, peeled off and scattered to be caused to pass through the recovery line 23 so that carbon nanofibers 15 52 is recovered in the separating apparatus 24.

A state where the adhered material is peeled off by the fluidizing material is explained with an illustrative diagram shown in Fig. 34. Fig. 34 is a schematic diagram of the chamber 122 - 1. As shown in Fig. 34, carbon nanofibers with a nano unit are adhered to an inner wall face 20 of the chamber 122 - 1 to form adhered material 125. The adhered material 125 is peeled off by physical influence occurring when the fluidizing material 11 flows down, and a portion thereof drop downwardly together with the fluidizing material 11 and a portion of peeled-off material 126 is conveyed to the recovery line 23 through the 25 recovery line 123 - 1 by the fluidizing gas and is separated in the

separating apparatus 24.

The recovered fluidizing material 11 can be recycled. Such a constitution is employed that the recovered fluidizing material is mixed with fresh fluidizing material 11 to be supplied into the fluidizing layer 5 reaction unit 12 by the fluidizing material supplying apparatus 127.

Thus, in this embodiment, even when the adhered material of carbon nanofibers 52 is produced, since the interior of the free board unit 17 are partitioned to the plurality of chambers, the flow rates in the chambers are sequentially adjusted, so that adhered material at any 10 place can be peeled off at any timing.

In this embodiment, means for partitioning the interior of the free board unit 17 to form the chambers is not limited to means for forming sectional shape in a direction crossing a vertical direction to a rectangular shape, as shown in Fig. 35(a), but it may be means for 15 making 8 chambers divided along the circumferential direction, for example, as shown in Fig. 35(b) or may be means for making 9 divided chambers formed in a regular square, as shown in Fig. 35(c). The number of divisions is not limited at all. The fluidizing material and the carbon nanofibers recovered by the recovery line 123 – 1 to 123 – 6 are 20 separated from each other in the separating apparatus, and the fluidizing material is recycled.

As explained above, according to this embodiment, in production of carbon nanofibers according to the fluidizing layer reaction mechanism, even if there are products adhered to a wall face 25 or a pipe interior, adhered material at any place can be peeled off and

recovered at any timing owing to a peeling-off phenomenon due to physical collision of fluidized materials by controlling a flow rate in the free board unit, so that a recovery efficiency of carbon nanofibers is improved. The staying time in the apparatus is controlled so that 5 production of carbon nanofibers with uniform quality is made possible.

Since uniform reaction inside the fluidizing layer reaction unit can be performed, catalyst and carbon material can react with each other under an excellent condition. At this time, since free board adhered material can be recovered at any timing and at any place, 10 uniformity of product can be prevented from lowering due to such a phenomenon that catalyst, carbon nanofibers and the like adhered to the free board unit fall off irregularly.

Fig. 36 is a diagram of a producing apparatus of carbon nanofibers where the free board unit is improved according to another 15 embodiment. Same members as those shown in Fig. 33 are attached with same numerals, and explanation thereof will be omitted.

In the embodiment, fluidizing materials with two or more particle diameter distributions are used in the producing apparatus of carbon nanofibers shown in Fig. 33.

20 As shown in Fig. 36, in this embodiment, coarse particle fluidizing material (particle diameter of 200 μm) 11-1, middle particle fluidizing material (particle diameter of 20 μm) 11-2, and a fine particle fluidizing material (particle diameter of 2 μm) 11-3 of three different kinds are used.

25 The fluidizing materials 11-1 to 11-3 recovered can be

recycled. In order to perform recycling, the recovered fluidizing materials and fresh fluidizing materials 11 - 1 to 11 to 3 are mixed to be supplied from fluidizing material supplying apparatus 127 - 1 to 127 - 3 into the fluidizing layer reaction unit 12.

5 In an ordinary reaction, scattering of particles to the free board unit 17 is prevented by using the coarsest particle fluidizing material 11 - 1.

When adhered material to a wall face of the free board portion 17 should be peeled off, peeling-off of the adhered material is 10 performed by using the fluidizing material with the middle particle diameter (20 μ m) which can be scattered toward the free board portion 17.

The coarsest particles 11 - 1, the middle particles 11 - 2 and the fine fluidizing material 11 - 3 are different in relationship between 15 the particle diameter and the flow rate of the fluidizing material. This relationship will be shown in Fig. 39.

When adhered material to a wall face of the downstream recovery line 23 should be removed, the adhered material is peeled off by using the fine particle fluidizing material 11 - 3.

20 Next, Fig. 37 is a diagram of one example of a fluidizing material separating apparatus for each particle diameter of fluidizing material separated in the cyclone 24. As shown in Fig. 37, a fluidizing material separating apparatus 130 is provided with a sieve 132 provided within a recovery cylinder 131 in a direction generally perpendicular to a vertical 25 direction, and a gas supplying apparatus 134 that supplies inert gas

133 from a lower stage of the sieve 132, and the fluidized materials 11 separated by the cyclone are separated for each particle diameter and the carbon nanofibers 52 accompanied with the fluidizing materials 11 are separated from the fluidizing materials 11.

5 As shown in Fig. 37, the sieve 132 may be inclined such that a portion thereof on a recovery line supply port side (left side on the drawing) is lower than a portion thereof on an exhaust side (right side on the drawing), thereby improving the separating efficiency.

Fig. 38 is a diagram of an outline of another producing
10 apparatus of carbon nanofibers. Same members as those the
apparatuses of the embodiments shown in Fig. 33 and Fig. 36 are
attached with same numerals, and explanation thereof will be omitted.
As shown in Fig. 38, the producing apparatus of carbon nanofibers
according to this embodiment are provided with the fluidizing layer
15 reaction unit 12 that supplies carbon material 13 and catalyst 52 to
produce carbon nanofibers 52, the free board unit 17 that has a space
communicating with the fluidizing layer reaction unit 12, through which
fluidizing material 11 scatters and fall down, a fluidizing gas supplying
apparatus 19 that introduces and supplies fluidizing gas 18 fluidizing
20 material 11 into the fluidizing layer reaction unit 12, the
heating apparatus 20 that heats the fluidizing layer reaction unit 12 from
a periphery thereof, a recovery line 23 that recovers fluidizing material
11 and carbon nanofibers 52 scattered from the free board unit 17, and
the separating apparatus 24 that separates the fluidizing material 11
25 and the carbon nanofibers 52 recovered in the recovery line 23 from

each other, where a gas supplying apparatus 142 which drops and supplies inert seal gas 141 with a temperature lower than that in the apparatus from a periphery of a top portion 14 a of the free board unit 17 into the free board unit 17 is provided.

5 By providing the seal gas 141, gas flowing down along the wall face further increases the flow of the fluidizing material, so that adhered material such as carbon nanofibers adhered to the wall face can be peeled off. It is further suitable that the gas blow is constituted to perform blow gas along the wall face.

10 The seal gas is not limited to the low temperature gas, but it may be high temperature gas. Thereby, in case of the low temperature gas, falling-off of fluidizing material particles is promoted due to reduction of a flow rate owing to a cooling effect. On other hand, in case of the high temperature gas, a source for adhesive force of the 15 adhering layer is removed by decomposition, vaporization, burning or the like.

Such a constitution can be employed that not only inert gas but also, for example, O₂, steam, CO₂ may be blown. These gases may be used alone or in a combination of two or more gases.

20 Fig. 39 is a diagram of an outline of another producing apparatus of carbon nanofibers. Same members as those the apparatuses of the embodiments shown in Fig. 33 and Fig. 36 are attached with same numerals, and explanation thereof will be omitted. As shown in Fig. 39, the producing apparatus of carbon nanofibers 25 according to the embodiment has a constitution that a cooling unit 143

that cools a peripheral wall of the free board unit 17 near a top portion thereof or gas or both thereof is provided instead of supplying seal gas in the apparatus shown in Fig. 38.

By cooling an upper portion inside the free board unit 17, as
5 shown in Fig. 42, since the flow rate decreases and does not exceed U_t , scattering toward the recovery line side does not occur and flowing-down along the wall face arises, so that adhered material of carbon nanofibers adhered to the wall face can be peeled off.

Instead of the cooling unit, a heating apparatus may be
10 provided.

Next, Fig. 43 is a diagram of another example of an apparatus for producing carbon nanofibers. Same members as members in the producing apparatus of carbon nanofibers shown in Fig. 16 are attached with same numerals and explanation thereof will be omitted. As shown
15 in Fig. 43, the producing apparatus of carbon nanofibers is provided with a fluidizing layer reaction unit 12 in which fluidizing material 11 has been charged, the raw material supplying apparatus 14 that supplies carbon raw material 13 into the fluidizing layer reaction unit 12, a catalyst supplying apparatus 101 that supplies catalyst 51 into the
20 fluidizing layer reaction unit 12, the fluidizing gas supplying apparatus 19 that supplies fluidizing gas 18 fluidizing fluidizing material 11 inside the fluidizing layer reaction unit 12, the heating apparatus 20 that heats the fluidizing layer reaction unit 12, the recovery line 23 that recovers carbon nanofibers 52 produced from the fluidizing layer reaction unit 12
25 and fluidizing material, the separating apparatus 24 that separates the

fluidizing material 11 and the carbon nanofibers 52 recovered in the recovery line 23, and a recirculating line 152 provided with a circulating unit 151 that recirculates the separated fluidizing material 11 into the fluidizing layer reaction unit 12.

5 By recirculating the fluidizing material 11 into the fluidizing layer reaction unit 12 through the recirculating line 152, adhesion of non-reacted product of the like into the recovery line 23 is prevented and carbon nanofibers 52 adhered to the non-reacted product can be peeled off and recovered, so that the recovery efficiency of carbon 10 nanofibers can be improved. As the circulating unit 151, a known unit such as an ejector can be used.

As a fluidizing bed reaction type for the fluidizing layer reaction unit 12, there are a bubble type fluidizing layer type and a jet flow type fluidizing layer type, and any one thereof can be used in the present 15 invention.

Next, Fig. 44 is a schematic diagram of another apparatus for producing carbon nanofibers. As shown in Fig. 44, such a constitution is employed that a plurality of drawing-out ports 161, which are drawing-out units for carbon nanofibers and fluidizing material 11 from 20 the fluidizing layer reaction unit 12 are provided in a vertical direction of a furnace and different carbon nanofibers are recovered by separating apparatuses 24B, 24C in the producing apparatus of carbon nanofibers shown in Fig. 41. Thereby, carbon nanofibers with different properties can be drawn out based upon a fluidizing time of the fluidizing layer 25 reaction unit 12.

Next, Fig. 45 is a schematic diagram of another apparatus for producing carbon nanofibers. As shown in Fig. 45, by supplying catalyst metals 51 and fluidizing gas 18 supplied to the fluidizing layer reaction unit from a bottom portion side of a furnace and supplying 5 carbon raw material 13 on a downstream side thereof (an outlet side of the reaction unit), more stable catalyst performance can be developed.

For example, when the catalyst metal is bimetal (Co/Mo) catalyst, in such a situation that respective Co component and Mo component are supplied to a furnace in their liquefied states and thereafter bimetal 10 metal is formed, after the catalyst is produced sufficiently as bimetal, the catalyst is caused to contact with and react with the carbon material 13, so that the reaction efficiency is improved.

INDUSTRIAL APPLICABILITY

15 As described above, the producing method of carbon nanofibers according to the present invention can produce carbon nanofibers with high purity efficiently with a high yield by producing carbon nanofibers using fine particles, allows industrial mass production and it is suitable for producing inexpensive carbon nanofibers.
